How to cope with Water Scarcity?

- 1. Technology, efficiency, and reuse (expensive)?
- 2. Curtail economic growth (too expensive)?
- 3. Political reallocation of water to most valuable uses (who decides)?
- 4. Economic reallocation of water resources using prices and water rights (political barriers and high transaction costs)?
- 5. Compromise our social, environmental, or economic values?
- 6. <u>Outsource largest and least valuable water uses?</u>

What are the values of water, to whom, how do we assess them in relation to hydrology, and how are we currently using #6 to solve the problem? A Complex Systems problem... Three types of networks intersect at a specific process node in a true Coupled Natural-Human System network:

- resource production (+ or -)
- trade or exchange (money, goods, services)
- value production (+ or -)

RESOURCES r		PROCESSES i		VALUES a
All physical resources relevant to values and actions <u>examples</u> : Land Surface Water Ground Water Air Fish and Game Oceans Forests Nutrients Pollutants Minerals Fuels and Energy Sources	Apply "Footprint" methodology to associate Actions with Resource Footprints	All human actions affecting resources and values <u>examples</u> : Power Supply Agricultural Municipal Industrial Water Supply	Apply "Impact" methodology to associate Actions with their Value Impacts	All values affected by actions and resources examples: Social Economic Environmental

Embedded Resource Impact Accounting (ERA): A network theory for complex CNH's

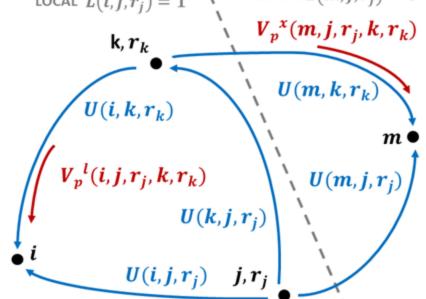

<u>Net Systemic Impact (footprint) of a Process, E</u>: the sum of the Direct (U) and indirect (V) network impacts of a process on a stock of interest, conditioned on a local/external (*I/x*) boundary

$$E = U^{l} + U^{x} + V^{l}_{IN} - V^{l}_{OUT} + V^{x}_{IN} - V^{x}_{OUT}$$

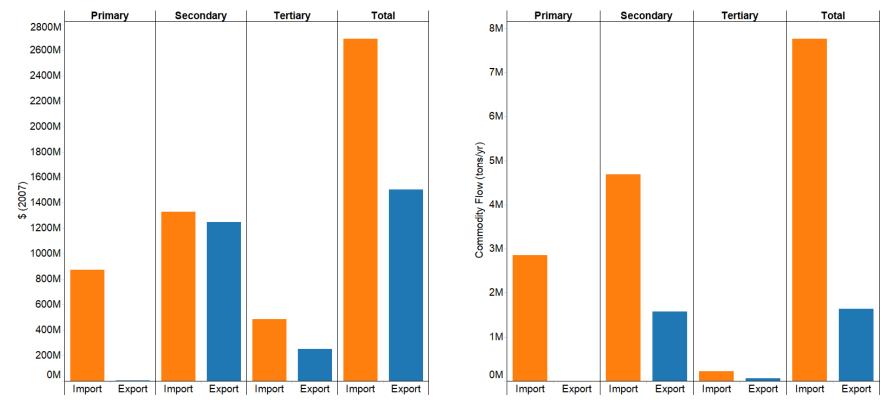

"<u>Virtual Water</u>" (Allan, 1993) is a special single-type network case of ERA. ERA is itself a special case of I/O and LCA, which are also network concepts. LOCAL $L(i,j,r_i) = 1$ NON-LOCAL $L(m,j,r_j) = 0$

The foundation of ERA is the *partial embedded resource impact* V_p ; the sum across intermediaries *k* and r_k is the net indirect impact *V*

$$V_p(i,j,r_j,k,r_k) = \frac{U(i,k,r_k)}{\sum_n U(n,k,r_k)} * U(k,j,r_j)$$

Commodity Inputs and Output By Distance

Flagstaff Water Footprint By Economic Sector

- Flagstaff's indirect water consumption (53,996 ac-ft per year) occurs in lower economic sectors
 - Resource intensive industries: agriculture
 - Lower value intensity
- Flagstaff's direct water consumption (8,553 ac-ft per year) supports higher level economic sectors
 - Less resource intensive: Education, finance, high value manufacturing
 - Higher value intensity

0											Φ 0.00	Indirect	Direct	Indirect	Direct	Indirect	Direct	Indirect	Direct
	Indirect	Direct																	

- Flagstaff's indirect water demand more than 6x greater than direct water consumption
- Value Intensity of Flagstaff's direct consumption highest in secondary sector
- Value Intensity of Flagstaff's indirect water demand highest in tertiary sector
- Overall, Flagstaff imports lower value water (indirect) and exports water at higher value (direct)
