

# Perennial Plant Species Richness, Diversity and Plant-Preferences in Phoenix – A Spatial Model For Prediction

- Anandamayee Majumdar, Corinna Gries, Jason Walker, Alexander Buyantuev, Nancy Grimm

**Dependent variables:** Perennial Plant Species counts, for 38 species, for 144 spatial locations.

**Independent variables significant in our model:**

For every location, ever in agriculture(0-1), elevation, income.

Challenges met in our model: Multivariate Spatial count data; Non-Gaussian model; Spatial GLMM used; Spatial heterogeneity due to different land-use; Nonstationarity; Dimensionality(5472 data points), Model comparison; Prediction of Diversity, Richness, Intensity of species; Prediction(Plant Preference).

Statistical Modeling: A Non-stationary Spatial Generalized Linear Mixed Model (SGLMM) was used.

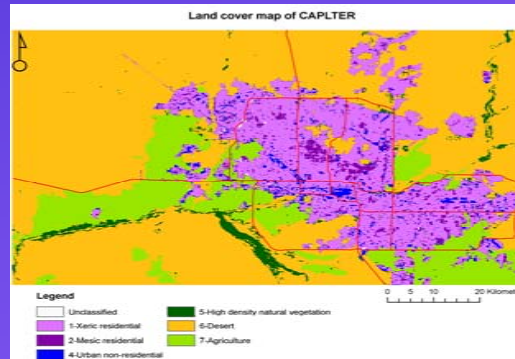

Based on the model we generated spatial intensities of **Larrea Tridentata**(Left image) and **Pennisetum setaceum** (Right image)

**\*\*LIGHTER is HIGHER.**

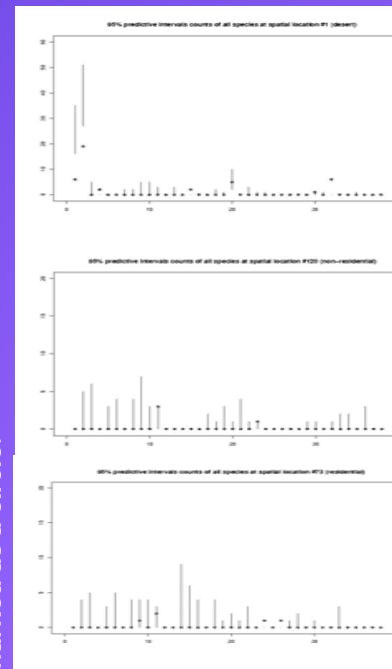

Land-use map of Phoenix 2000

**Landuse types:** Urban residential, Urban non-residential, Desert.

**Data:** 144 spatial locations. 38 Species.

95% prediction intervals for each of 38 species at 3 distinct locations: Desert (top), Non-Residential(mid), Residential(bottom). Actual count is marked as a circle.

The regression coeffs. for each of 38 species for Ever in ag. For Desert points(top), Non-residential points(middle) Residential points(bottom)

Predicted Richness of Perennial Species

Predicted Shannon-Weiner Diversity
